## ABSTRACT

This report examines the performance of wireless and device-to-device communication by comparing theoretical predictions with experimental results in three scenarios: WiFi-only, Ethernet-only, and a mixed configuration. Using iperf3 and Wireshark, we measured goodput and analyzed its variability under different conditions. The experimental data were contrasted with theoretical estimates based on protocol efficiencies and network overheads. Our findings underscore Ethernet's stability and highlight the challenges of WiFi's shared medium and half-duplex constraints.

## 1 BACKGROUND AND OBJECTIVES

- 1 This laboratory evaluates and compares the performance of wired  
2 and wireless communication in a local area network by setting  
3 up three scenarios: both devices on WiFi, both on Ethernet, and a  
4 mixed configuration with one on each.
- 5 The main objectives of the lab are to:
  - 6 • Measure goodput using iperf3.
  - 7 • Analyze the variability and stability of the connection in each  
8 scenario by collecting data over multiple test runs.
  - 9 • Compare the experimental results against theoretical predictions  
10 based on protocol efficiencies and network overhead.
  - 11 • Investigate potential sources of performance degradation in wire-  
12 less communication, such as interference, half-duplex operation,  
13 and shared medium limitations.
- 14 These experiments provide practical insights into the strengths  
15 and limitations of both Ethernet and WiFi, crucial for optimizing  
16 mixed network performance.

## 2 METHODOLOGY AND CONCEPTS

- 17 This section outlines the experimental setup, the tools employed for  
18 the measurements, and the theoretical basis for estimating goodput.

### 2.1 Selected Tools

- 20 To evaluate the performance of both Ethernet and WiFi connections,  
21 we utilized several specialized tools:
  - 22 • **iperf3**: Used to generate traffic and measure goodput in both  
23 TCP and UDP modes. By executing repeated tests, iperf3 provides  
24 key metrics such as minimum, maximum, average, and standard  
25 deviation of the throughput.
  - 26 • **Wireshark**: Used to capture and analyze network traffic, Wire-  
27 shark helped inspect data flows, identify frames, and validate  
28 results. It also generated useful charts for analyzing TCP streams.

<sup>\*</sup>The authors collaborated closely in developing this project.

<sup>†</sup>All the authors are students at Politecnico di Torino, Turin, Italy.

- **Automation Script**: A Python script was developed to automate  
29 the entire measurement process. This script manages both server  
30 and client modes of iperf3, logs output in JSON, CSV, and plain  
31 text formats, and computes summary statistics. The script accepts  
32 several command-line flags, as detailed in the Appendix.  
33

### 2.2 Goodput Estimation

Goodput represents the rate at which useful data is delivered to the application layer, excluding protocol overheads and retransmitted packets. The theoretical estimation of goodput is based on the efficiency of the protocol and the capacity of the network link:

$$G \leq \eta_{\text{protocol}} \times C,$$

where  $C$  is the capacity of the bottleneck link and  $\eta_{\text{protocol}}$  is the protocol efficiency.

1. For **Ethernet**, the efficiency for TCP is computed as:

$$\eta_{TCP}^{Eth} = \frac{MSS}{MSS + \text{TCP headers} + \text{IP headers} + \text{Eth. overhead}},$$

with the Maximum Segment Size (MSS) defined as the MTU minus the headers. For a standard MTU of 1500 bytes, we obtain:

- $MSS \approx 1460$  bytes (after subtracting 20 bytes for the IP header and 20 bytes for the TCP header),  
44
- An additional Ethernet overhead of approximately 38 bytes.  
45

Thus, the efficiency for TCP over Ethernet is approximately:  
46

$$\eta_{TCP}^{Eth} \approx \frac{1460}{1460 + 20 + 20 + 38} \approx 94.9\%.$$

Similarly, the efficiency for UDP is computed as follows. Since UDP has an 8-byte header, its MSS is given by:  
48

- $MSS \approx 1472$  bytes (after subtracting 20 bytes for the IP header and 8 bytes for the UDP header).  
50

Thus, the efficiency for UDP over Ethernet is given by:  
52

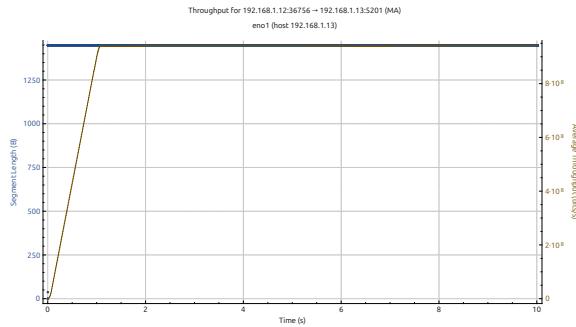

$$\eta_{UDP}^{Eth} \approx \frac{1472}{1472 + 20 + 8 + 38} \approx 95.7\%.$$

2. For **WiFi**, additional factors must be considered due to its half-duplex nature and the inherent overhead of the 802.11 protocol (e.g., control frames, retransmissions, and channel contention). In the case of **TCP over WiFi**, the effective efficiency is typically around 80% under optimal conditions. This lower efficiency arises from the extra overhead associated with TCP's connection-oriented features—such as congestion control, flow control, and the guarantee of in-order delivery—which require additional control packets and retransmissions.  
53
- In contrast, **UDP over WiFi** generally attains an efficiency of approximately 85–90% by avoiding these mechanisms, leading to a simpler and faster data transmission process.  
62

<p>65        and</p> <p>66        These theoretical estimates set an upper bound on the achievable 67        goodput, against which our experimental results are compared. 68        Discrepancies between theory and practice are primarily due to 69        dynamic environmental factors, such as interference, channel vari- 70        ability, and the inherent limitations of wireless communication.</p> <p><b>3 EXPERIMENTAL SETUP AND TEST CASES</b></p> <p><b>3.1 Equipment and Configuration</b></p> <p>72        In this section, we describe the hardware and software configura- 73        tion used to perform our network performance measurements. 74        Table 1 summarizes the main devices, their interfaces, and relevant 75        specifications.</p> <p><b>Device Key Specifications</b></p> <hr/> <p><b>PC1</b>      <b>Victus 16-s1005nl Notebook</b>  <i>Operating System:</i> Ubuntu 24.04.2 LTS  <i>Ethernet Interface:</i> Realtek RTL8111/8168/8211/8411  <i>Wireless Interface:</i> Realtek RTL8852BE (802.11ax)   2x2</p> <hr/> <p><b>PC2</b>      <b>Microsoft Surface Laptop Go 3</b>  <i>Operating System:</i> Ubuntu 24.10  <i>Ethernet Interface:</i> via Anker PowerExpand+ USB-C Hub  <i>Wireless Interface:</i> Intel Alder Lake-P CNVi (802.11ax)   2x2</p> <hr/> <p><b>Router</b>     <b>Vodafone Power Station Wi-Fi 6</b>  <i>Ethernet Ports:</i> 4 x 1 GbE ports  <i>Wi-Fi:</i> Dual-band 802.11ax (2.4 GHz   2x2, 5 GHz   4x4)</p> <hr/> <p><b>Cables</b>     CAT.5E (up to 1 Gbps)</p>	<p><b>1. Both Ethernet:</b> 85              In this scenario, both PC1 and PC2 are connected to the router 86              via CAT.5E cables, providing a nominal link capacity of 1 Gbps. 87              The efficiency for Ethernet is calculated as follows: 88</p> $\eta_{TCP}^{Eth} \approx \frac{1460}{1460 + 20 + 20 + 38} \approx 94.9\%, \quad 89$ $\eta_{UDP}^{Eth} \approx \frac{1472}{1472 + 20 + 8 + 38} \approx 95.7\%. \quad 90$ <p>Thus, the expected goodput is: 90</p> $G_{TCP}^{Eth} \leq 0.949 \times 1000 \text{ Mbps} \approx 949 \text{ Mbps}, \quad 91$ $G_{UDP}^{Eth} \leq 0.957 \times 1000 \text{ Mbps} \approx 957 \text{ Mbps}. \quad 91$ <p><b>2. Both Wi-Fi:</b> 92              For this configuration, both devices use their wireless interfaces 93              (802.11ax) to connect to the router. Although the nominal Wi- 94              Fi link speed is assumed to be approximately 1.2 GbEbps, the 95              half-duplex nature of Wi-Fi effectively halves the throughput 96              available for data transfer. Assuming a Wi-Fi efficiency factor 97              of about 80%, the expected goodput for TCP is: 97</p> $G_{TCP}^{WiFi} \leq 0.80 \times 1.2 \text{ Gbps} \times \frac{1}{2} \approx 480 \text{ Mbps}, \quad 98$ <p>and similarly for UDP, with a different efficiency factor: 99</p> $G_{UDP}^{WiFi} \leq 0.85 \times 1.2 \text{ Gbps} \times \frac{1}{2} \approx 510 \text{ Mbps}. \quad 99$ <p><b>3. Mixed Scenario:</b> 100              In this configuration, one device (PC1) is connected via Ethernet 101              while the other (PC2) uses its Wi-Fi interface. Since only one 102              side is on Wi-Fi, we average the Wi-Fi portion and the Ethernet 103              portion rather than halving for two Wi-Fi paths. Hence, the 104              expected goodput is: 104</p> $G_{TCP}^{Mixed} \leq \frac{(0.80 \times 1.2 \text{ Gbps}) + (0.949 \times 1.0 \text{ Gbps})}{2} \approx 955 \text{ Mbps}, \quad 105$ $G_{UDP}^{Mixed} \leq \frac{(0.85 \times 1.2 \text{ Gbps}) + (0.957 \times 1.0 \text{ Gbps})}{2} \approx 989 \text{ Mbps}. \quad 106$ <p>These calculations provide the theoretical upper bounds for good- 106              put in each scenario. The experimental results, obtained via auto- 107              mated measurements using the provided Python script, are com- 108              pared against these predictions to evaluate real-world performance. 109</p>																																			
<p><b>4 ANALYSIS AND FINDINGS</b></p> <p><b>4.1 TCP Performance</b> 110</p> <p>The performance tests using TCP reveal several noteworthy trends. 111              The analysis for TCP performance in different scenarios is organized 112              as follows: 113</p>																																				
<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th rowspan="2" style="text-align: center;">Test</th> <th colspan="5" style="text-align: center;">TCP: Goodput per flow (Mbps)</th> </tr> <tr> <th style="text-align: center;">Prediction</th> <th style="text-align: center;">Average</th> <th style="text-align: center;">Min</th> <th style="text-align: center;">Max</th> <th style="text-align: center;">Std</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">Both WiFi</td> <td style="text-align: center;">480</td> <td style="text-align: center;">434.7</td> <td style="text-align: center;">396.3</td> <td style="text-align: center;">461.96</td> <td style="text-align: center;">22.5</td> </tr> <tr> <td style="text-align: center;">Both Ethernet</td> <td style="text-align: center;">949</td> <td style="text-align: center;">939.6</td> <td style="text-align: center;">938.2</td> <td style="text-align: center;">942.7</td> <td style="text-align: center;">1.5</td> </tr> <tr> <td style="text-align: center;">Mixed</td> <td style="text-align: center;">?</td> <td style="text-align: center;">663.7</td> <td style="text-align: center;">619.2</td> <td style="text-align: center;">698.86</td> <td style="text-align: center;">26.6</td> </tr> <tr> <td style="text-align: center;">Shared Capacity</td> <td style="text-align: center;">?</td> <td style="text-align: center;">536.8</td> <td style="text-align: center;">440.5</td> <td style="text-align: center;">722.2</td> <td style="text-align: center;">112</td> </tr> </tbody> </table>		Test	TCP: Goodput per flow (Mbps)					Prediction	Average	Min	Max	Std	Both WiFi	480	434.7	396.3	461.96	22.5	Both Ethernet	949	939.6	938.2	942.7	1.5	Mixed	?	663.7	619.2	698.86	26.6	Shared Capacity	?	536.8	440.5	722.2	112

<p><b>Table 3:</b> TCP Results (Client → Server)</p>																																				

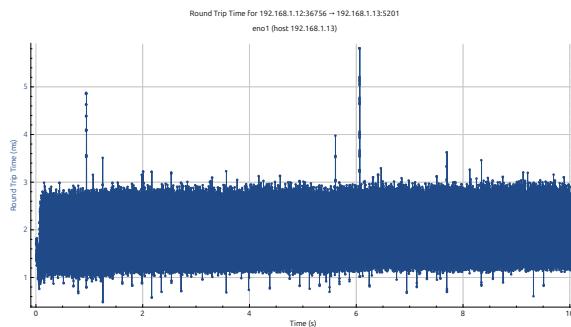

114 **1. Both Ethernet:**

115 Figure 1 shows the TCP throughput measured in the Ethernet scenario. The graph reveals a rapid ramp-up in throughput  
 116 during the first few seconds, followed by a stable transmission  
 117 rate that approaches the theoretical value.  
 118

**Figure 1:** TCP Throughput in the Ethernet Scenario.

119 Figure 2 illustrates the round-trip time (RTT), which remains  
 120 very low (typically within a few milliseconds), highlighting the  
 121 minimal latency in wired connections.

**Figure 2:** TCP Round Trip Time in the Ethernet Scenario.

122 Furthermore, the I-O graph (Fig. ??) confirms a consistent packet  
 123 flow with little variation, indicating that the Ethernet setup  
 124 effectively utilizes the available capacity.

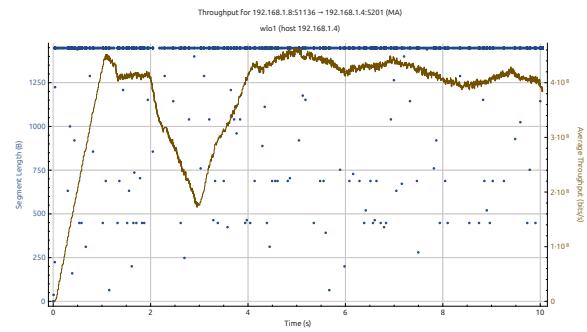

125 Overall, the Ethernet scenario demonstrates a near-ideal per-  
 126 formance with high throughput and minimal latency, closely  
 127 matching the theoretical predictions.

128 **2. Both WiFi:**

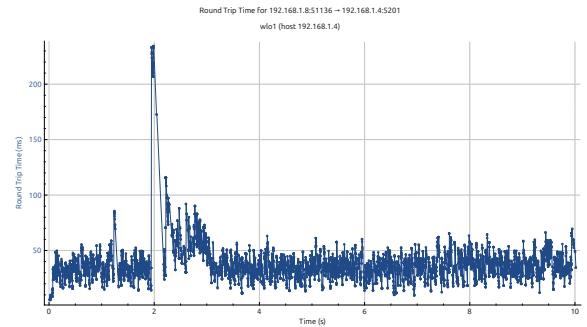

129 In the WiFi scenario, the throughput graph (Fig. 3) shows an  
 130 initial ramp-up phase during the first 2 seconds, after which the  
 131 throughput fluctuates around an average value that is signifi-  
 132 cantly lower than the theoretical maximum of approximately  
 133 347 Mbps. These fluctuations suggest that protocol overhead,  
 134 wireless interference, and the half-duplex nature of WiFi ad-  
 135 versely affect performance.

137 The round-trip time (RTT) measurements (Fig. 4) reveal RTT  
 138 values ranging from about 50 to 200 ms, indicating intermittent  
 139 delays likely due to congestion and contention in the wireless  
 140 medium.

142 Furthermore, the I-O graph (Fig. ??) illustrates a variable num-  
 143 ber of transmitted packets per interval, reflecting the dynamic

**Figure 3:** TCP Throughput in the WiFi Scenario.

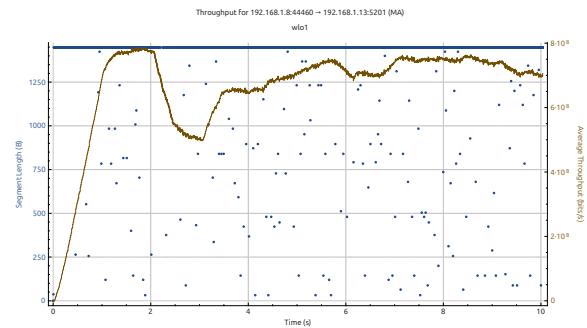

**Figure 4:** TCP Round Trip Time in the WiFi Scenario.

nature of WiFi communication where channel conditions and  
 144 collision avoidance mechanisms influence performance.  
 145 Overall, while the theoretical capacity for TCP over WiFi is  
 146 estimated to be around 347 Mbps, the experimental data indi-  
 147 cate that real-world factors substantially reduce the effective  
 148 throughput.  
 149

3. Mixed:

150 Figure 5 displays the TCP throughput for the mixed configura-  
 151 tion. The graph shows that the throughput reaches a stable level  
 152 after an initial ramp-up phase, although it remains below the  
 153 Ethernet scenario and is consistent with the expected reduction  
 154 due to the reliance on the wireless link.  
 155

**Figure 5:** TCP Throughput in the Mixed Ethernet/WiFi Scenario.

The round-trip time (RTT) measurements, presented in Figure 6,  
 157 indicate moderate latency, with RTT values generally remain-  
 158 ing within a lower range compared to the pure WiFi scenario.  
 159 This suggests that the wired segment helps in reducing overall  
 160

161 latency.  
162

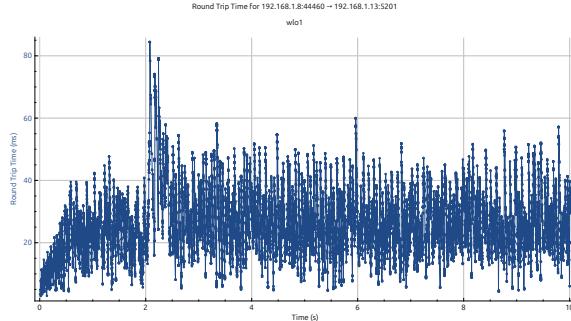

Figure 6: TCP Round Trip Time in the Mixed Ethernet/WiFi Scenario.

163 The I-O graph for TCP (Fig. ??) shows a relatively steady packet  
164 flow over the test intervals, confirming that the mixed config-  
165 uration maintains a stable performance despite the inherent  
166 variability of the wireless link.

167 **3a. Shared Capacity:**  
168 In this scenario, a third host connected to the same access point  
169 was concurrently downloading the film "Natale a Rio" (directed  
170 by Neri Parenti), which introduced significant interference dur-  
171 ing the tests. This additional traffic compromised the available  
172 network capacity, leading to degraded performance. Figure ??  
173 shows the TCP throughput under this shared capacity condi-  
174 tion. Compared to the mixed scenario without interference, the  
175 throughput exhibits a notable decrease. The average throughput  
176 is lower, reflecting the reduced available bandwidth caused by  
177 the competing download traffic.

178 The round-trip time measurements (Fig. ??) indicate increased  
179 variability and slightly elevated latency. Although the RTT  
180 values remain relatively moderate, the fluctuations suggest that  
181 the network experiences occasional congestion and delays as a  
182 result of the third host's activity.

183 The I-O graph for TCP (Fig. 7) further confirms the impact of  
184 the interference. The graph displays irregular intervals and a  
185 lower packet transmission rate compared to the mixed scenario  
186 without the additional load, demonstrating how the extra traffic  
187 disrupts the steady flow of data.

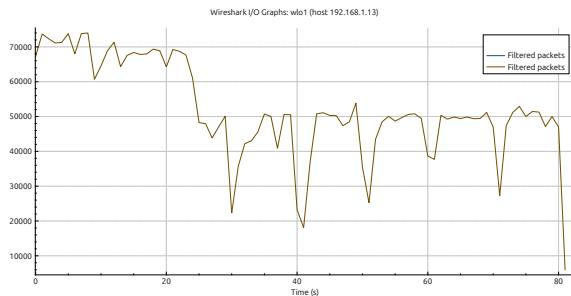

Figure 7: Wireshark I-O Graph for TCP in the Shared Capacity Scenario.

## 188 4.2 UDP Performance

189 The UDP tests offer an insightful comparison to the TCP results  
190 by eliminating congestion control and acknowledgment overhead.

The analysis for UDP performance across different scenarios is  
structured as follows: 191  
192

Test	UDP: Goodput per flow (Mbps)				
	Prediction	Average	Min	Max	Std
Both WiFi	480	487.8	453.1	499.9	15.8
Both Ethernet	957	952.8	948.3	954.6	1.73
Mixed	?	674.9	636.6	717.8	28
Shared Capacity	?	472.1	355.9	699.1	121.1

Table 4: UDP Results (Client → Server)

### 193 **1. Both Ethernet:**

In the Ethernet configuration, the I-O graph for UDP indicates  
194 a steady packet flow, with minimal fluctuations compared to  
195 the WiFi scenario. 196

The throughput achieved is very close to the theoretical pre-  
197 diction, confirming that the wired setup reliably supports high-  
198 speed data transfer. The absence of retransmission or congestion  
199 control overhead in UDP further contributes to this consistent  
200 performance. 201

In summary, the wired (Ethernet) tests demonstrate that both  
202 TCP and UDP protocols achieve performance levels very close  
203 to their theoretical capacities, with TCP showing stable through-  
204 put and low latency, and UDP exhibiting a consistent packet flow  
205 and high throughput. This confirms that, in a controlled wired  
206 environment, network performance is minimally impacted by  
207 protocol overhead or environmental factors. 208

### 209 **2. Both WiFi:**

In the WiFi scenario, the I-O graph for UDP demonstrates a  
210 more consistent packet flow compared to TCP. However, despite  
211 the smoother transmission, the overall throughput remains  
212 below the theoretical upper bound. The lack of retransmission  
213 mechanisms in UDP allows for slightly higher instantaneous  
214 throughput; nonetheless, factors like interference and channel  
215 contention continue to impact performance. 216

A direct comparison between TCP and UDP in the WiFi scenario  
217 shows that UDP can achieve marginally higher throughput due  
218 to its reduced overhead. Nonetheless, both protocols suffer from  
219 real-world limitations that prevent them from reaching their  
220 theoretical capacities. This discrepancy between capacity and  
221 theoretical goodput emphasizes the impact of wireless inter-  
222 ference, channel contention, and protocol-specific overhead on  
223 performance. 224

### 225 **3. Mixed:**

In the mixed scenario, the UDP I-O graph indicates a consistent  
226 flow of packets, similar to the TCP case but with slightly less  
227 variability due to the absence of congestion control. 228

The throughput observed is in line with expectations given that  
229 only the wireless link acts as the bottleneck. 230

In summary, the mixed scenario demonstrates that while the  
232 presence of a wired connection on one end improves overall  
233 latency and stability compared to a full WiFi configuration,  
234 the performance remains primarily constrained by the wireless  
235 link. Both TCP and UDP protocols achieve throughput values  
236

237 that are consistent with theoretical predictions for a mixed  
238 Ethernet/WiFi environment.

239 3a. **Shared Capacity:**

240 The UDP tests under the shared capacity scenario also reveal the  
241 negative impact of the additional download traffic. Although  
242 UDP is less affected by protocol overhead, the increased con-  
243 tention for the wireless medium leads to degraded performance.  
244 The UDP performance in this scenario is indirectly reflected  
245 in the I-O graph. The steady flow of packets observed in a  
246 non-interfered environment is disrupted, resulting in a lower  
247 effective throughput.

248 Despite the inherent resilience of UDP to retransmission de-  
249 lays, the interference from the third host causes a noticeable  
250 reduction in performance. The graph shows that the packet flow  
251 is not as consistent, further underlining the effects of shared  
252 capacity when additional traffic is present.

253 Overall, the shared capacity scenario clearly demonstrates that  
254 when a third host generates significant traffic (as in the case  
255 of streaming a movie), the available network resources are fur-  
256 ther divided, leading to performance degradation for both TCP  
257 and UDP protocols. This scenario highlights the importance of  
258 considering real-world usage patterns and interference when  
259 designing and evaluating network performance.

## 5 CONCLUSION

260 In this project, we evaluated the performance of network commu-  
261 nication under various scenarios using both wired (Ethernet) and  
262 wireless (WiFi) connections. Our experimental results, obtained  
263 through automated measurements with iperf3 and detailed packet  
264 analysis with Wireshark, were compared against theoretical pre-  
265 dictions of goodput for both TCP and UDP protocols.

266 Overall, the Ethernet scenario demonstrated near-ideal perfor-  
267 mance, with throughput and latency closely matching the theoreti-  
268 cal values. This confirms that a controlled wired environment can  
269 efficiently utilize available bandwidth with minimal interference. In  
270 contrast, the WiFi scenario showed a significant performance drop,  
271 with fluctuations in throughput and increased latency due to the in-  
272 herent limitations of wireless communication such as interference,  
273 contention, and the half-duplex nature of WiFi.

274 The mixed scenario, where one device is connected via Ethernet  
275 and the other via WiFi, presented an intermediate case. Here, while  
276 the wired segment helped in reducing latency and stabilizing per-  
277 formance, the overall throughput remained limited by the wireless  
278 link. Finally, the shared capacity scenario—where an additional host  
279 engaged in heavy traffic (streaming a movie)—further degraded per-  
280 formance for both TCP and UDP tests. This clearly highlights the  
281 impact of network congestion and shared medium contention on  
282 real-world performance.

283 These findings emphasize the importance of considering environ-  
284 mental and traffic-related factors when designing and optimizing  
285 network infrastructures. While theoretical models provide useful  
286 upper bounds, actual network performance is influenced by a range  
287 of practical factors that must be taken into account for effective  
288 network planning and troubleshooting.

## A APPENDIX

### 289 Server Mode Initialization

```
290     def run_server():
291         """Run iperf3 server with clean output handling.
292             """
293         server_logger.info("Starting iperf3 server...")
294
295         proc = subprocess.Popen(
296             ["iperf3", "-s", "-J"],
297             stdout=subprocess.PIPE,
298             stderr=subprocess.PIPE,
299             text=True,
300             bufsize=1,
301         )
302         # Handle server output and errors in a separate
303         # thread...
```

Listing 1: Excerpt for server mode initialization.

### 304 Client Mode Execution and Reporting

```
305     def run_client(server_ip, udp=False, bitrate="1M",
306                     iterations=10):
307         """Run iperf3 client tests and generate reports.
308             """
309         for i in range(iterations):
310             cmd = ["iperf3", "-c", server_ip, "-J", "-t"
311                   , "10", "-i", "1"]
312             if udp:
313                 cmd.extend(["-u", "-b", bitrate])
314
315             result = subprocess.run(
316                 cmd,
317                 capture_output=True,
318                 text=True,
319                 check=True
320             )
321
322             data = json.loads(result.stdout)
323             # Extract test data, compute statistics, and
324             log results...
```

Listing 2: Excerpt for client mode execution.

### 325 Logging and Output Management

```
326     def setup_logger(log_file, name):
327         logger = logging.getLogger(name)
328         logger.setLevel(logging.DEBUG)
329         handler = logging.FileHandler(log_file)
330         formatter = logging.Formatter(
331             '%(asctime)s - %(levelname)s - %(message)s'
332         )
333         handler.setFormatter(formatter)
334         logger.addHandler(handler)
335     return logger
```

Listing 3: Excerpt for logging setup.

336 These snippets illustrate how the script handles server mode ini-  
337 tialization, client tests (both TCP and UDP), and logging. Error  
338 handling, multithreaded stderr management, and CSV report gen-  
339 eration are also included in the complete script.
